

RABBET MOUNTED COMBUSTOR

**[0001]** The U.S. Government may have certain rights in this invention in accordance with Contract No. DAAE07-00-C-N086 awarded by the Department of the Army.

BACKGROUND OF THE INVENTION

**[0002]** The present invention relates generally to gas turbine engines, and, more specifically, to combustors therein.

**[0003]** A typical gas turbine engine includes a multistage compressor for pressurizing air which is mixed with fuel in a combustor for generating hot combustion gases. The gases flow through a high pressure turbine (HPT) which extracts energy for powering the compressor. A low pressure turbine (LPT) extracts additional energy for providing output work, such as powering a fan in a turbofan aircraft engine application, or providing output shaft power in land-based or marine applications.

**[0004]** In designing a turbine engine for powering a military vehicle, such as a main battle tank, the size and weight of the engine must be as small as possible, which correspondingly increases the difficulty of integrating the various engine components for maximizing performance, efficiency, and life. For example, one engine being developed includes an exhaust heat exchanger or recuperator which uses the hot combustion gases discharged from the turbines for additionally heating the pressurized air discharged from the compressor for increasing engine efficiency. However, this hot pressurized air must also be used for cooling the combustor components themselves which further increases the complexity of the combustor design.

**[0005]** In the last two decades, a double-wall combustor design underwent considerable development effort which did not lead to commercial production thereof. Radially outer and inner combustion liners were supported from corresponding radially outer and inner annular supports. Compressor discharge air was channeled through apertures in the supports for impingement cooling the outer surfaces of the liners. The spent impingement air was then

1   channeled through film cooling and dilution holes in the liners for cooling the liners  
2   themselves, as well as providing dilution air for the combustion gases generated in the  
3   annular combustion chamber.

4   **[0006]**   A consequence of the double wall combustor design is the inherent difference in  
5   operating temperature between the liners and the surrounding supports. Differential  
6   operating temperatures result in differential thermal expansion and contraction of the  
7   combustor components. Such differential thermal movement occurs both axially and  
8   radially, as well as during steady state or static operation and during transient operation of  
9   the engine as power is increased and decreased.

10   **[0007]**   The liners must therefore be suitably mounted to their supports for accommodating  
11   differential thermal movement therebetween, while also minimizing undesirable leakage of  
12   the pressurized air coolant. The liners must be mounted concentrically with each other and  
13   with the supports to minimize undesirable variations in temperature distribution, both  
14   radially and circumferentially around the outlet end of the combustor as represented by the  
15   conventionally known pattern and profile factors.

16   **[0008]**   Liner alignment or concentricity with the turbine is therefore an important design  
17   objective for an annular combustor, and is rendered particularly more difficult due to the  
18   double-wall liner configuration. Liner alignment affects all aspects of the combustor  
19   performance including cooling thereof, dilution of the combustion gases, and turbine  
20   performance. And, liner mounting to the supports must minimize thermally induced stress  
21   therein for ensuring maximum life of the combustor during operation.

22   **[0009]**   The development combustor disclosed above was designed for proof-of-concept  
23   and lacked production features for the intended service life requirements in the tank  
24   application. For example, studs were welded to the outer liner and simply bolted to the outer  
25   support for mounting the outer liner thereto. In turn, the entire combustor was aft-mounted  
26   to a support casing through the outer combustor wall. This bolted design inherently fails to  
27   accommodate differential thermal movement between the liner and outer support and results  
28   in considerable thermal stresses during operation.

29   **[0010]**   Accordingly, it is desired to provide an improved double-wall combustor design for

1 accommodating differential thermal movement during operation while maintaining  
2 concentricity of liner support.

3

4

#### BRIEF DESCRIPTION OF THE INVENTION

5

6 **[0011]** A combustor includes an outer wall and an inner liner joined to an inner shell in  
7 turn mounted to an inner casing. The casing includes a first rabbet at an end flange in which  
8 is mounted a corresponding flange of the inner shell. The inner shell also includes a second  
9 rabbet which receives an end flange of the inner liner. The inner shell is trapped in the first  
10 rabbet by an inner retainer. And, the inner liner is trapped in the surrounding second rabbet  
11 for aft-mounting the liner and shell to the inner casing.

12

13

#### BRIEF DESCRIPTION OF THE DRAWINGS

14

15 **[0012]** The invention, in accordance with preferred and exemplary embodiments, together  
16 with further objects and advantages thereof, is more particularly described in the following  
17 detailed description taken in conjunction with the accompanying drawings in which:

18 **[0013]** Figure 1 is a partly sectional, schematic view of a gas turbine engine having one  
19 embodiment of a double-wall combustor for powering a land-based vehicle.

20 **[0014]** Figure 2 is an enlarged axial sectional view of the aft end of the combustor inner  
21 wall illustrated in Figure 1.

22 **[0015]** Figure 3 is an exploded view of the combustor aft inner mount illustrated in Figure  
23 2 showing schematically the assembly thereof, and disassembly for repair.

24

25

#### DETAILED DESCRIPTION OF THE INVENTION

26

27 **[0016]** Illustrated schematically in Figure 1 is a gas turbine engine 10 configured for  
28 powering a land-based vehicle, for example. The engine is axisymmetrical about a  
29 longitudinal or axial centerline axis 12, and includes multistage compressor 14 for

1   pressurizing air 16 during operation. The pressurized air is discharged from the compressor  
2   and mixed with fuel 18 in an annular combustor 20 for generating hot combustion gases 22.

3   **[0017]**   The combustion gases are discharged from the combustor into a high pressure  
4   turbine (HPT) 24 which extracts energy therefrom for powering the compressor. The high  
5   pressure turbine is conventional and includes an annular stator nozzle at the discharge end of  
6   the combustor which directs the combustion gases through a row of high pressure turbine  
7   rotor blades extending outwardly from a supporting rotor disk joined by a shaft to the  
8   compressor rotor.

9   **[0018]**   A low pressure turbine (LPT) 26 follows the HPT and conventionally includes one  
10   or more stator nozzles and rotor blade rows for extracting additional energy for powering an  
11   output driveshaft, which in turn drives a transmission in the exemplary military tank  
12   application.

13   **[0019]**   An exhaust heat exchanger or recuperator 28 receives the combustion gases from  
14   the LPT for in turn further heating the compressor discharge air suitably channeled thereto.  
15   The so-heated compressor discharge air is then channeled to the combustor for undergoing  
16   the combustion process, as well as providing cooling of the combustor components.

17   **[0020]**   The annular combustor illustrated in Figure 1 is axisymmetrical about the engine  
18   centerline axis 12 and is structurally supported from an annular outer casing 30. The  
19   combustor is an assembly of components further including an annular radially inner casing,  
20   or combustor case, 32 including a first or aft flange 34 and a second or forward flange 36 at  
21   opposite ends thereof, and annular header 38 disposed therebetween closely adjoining the  
22   casing forward flange 36.

23   **[0021]**   As shown in more detail in Figures 2 and 3, the inner casing 32 also includes an  
24   annular first rabbet 40 extending circumferentially around the casing aft flange 34 facing  
25   axially aft and radially outwardly.

26   **[0022]**   Referring again to Figure 1, the combustor further includes an annular, radially  
27   inner shell or support 42 disposed concentrically around the inner casing 32 and supported  
28   thereon. The inner shell includes a first or aft flange 44 and a second or forward flange 46 at  
29   opposite ends thereof, and an annular dome 48 therebetween closely adjoining the shell

1 forward flange 46. Again shown in more detail in Figures 2 and 3, the inner shell also  
2 includes an annular radially outer second rabbet 50 around the shell aft flange 44, with the  
3 shell aft flange itself being seated in the first rabbet 40.

4 **[0023]** The combustor illustrated in Figure 1 also includes an annular outer combustor wall  
5 52 suitably mounted to the shell forward flange 46 by a plurality of fasteners such as bolts.  
6 The outer wall 52 is an assembly of an outer shell and an outer combustion liner having  
7 suitable apertures therethrough for channeling the pressurized air 16 as a coolant  
8 therethrough during operation.

9 **[0024]** An annular, radially inner combustion liner 54 includes a first or aft flange 56 and a  
10 second or forward flange 58 at opposite ends thereof which mount the inner liner to the inner  
11 shell in another double-wall configuration spaced radially inwardly from the outer wall 52 to  
12 define therebetween an annular combustion chamber 60.

13 **[0025]** The forward flange 58 of the inner liner includes a radially outwardly facing slot  
14 that receives an L-shaped split retainer ring 62 which also seats in an axial groove at the  
15 junction of the inner shell and its dome for free-floating the inner liner to the inner shell to  
16 permit unrestrained differential thermal expansion and contraction relative to the aft end of  
17 the inner liner and shell. The liner aft flange 56, as best illustrated in Figure 2, is in the form  
18 of a radially inwardly extending rim which is seated in the second rabbet 50 of the inner  
19 shell. In turn, the shell aft flange 44 is also in the form of a radially inwardly extending rim  
20 which is seated in the first rabbet 40.

21 **[0026]** Accordingly, both the outer and inner double-walls and dome 48 defining the  
22 combustion chamber 60 are commonly supported from the combustor case or inner shell 42,  
23 which in turn is supported on the aft flange 34 of the inner casing 32 for providing  
24 aft-mounting of the combustor, with a corresponding loadpath to the supporting outer casing  
25 30. The forward flange 36 of the inner casing is suitably mounted to a corresponding flange  
26 of the outer casing using a row of fasteners such as bolts.

27 **[0027]** As shown in Figure 2, the shell aft flange 44 is simply seated in the first rabbet 40  
28 with a suitably close tolerance therebetween, and similarly, the liner aft flange 56 is simply  
29 seated in the second rabbet 50 with a suitably close tolerance therebetween. An annular

1 inner retainer 64 is fixedly joined to the casing aft flange 34 by bolt fasteners for example to  
2 axially trap the shell aft flange 44 around the first rabbet 40.

3 **[0028]** Similarly, an annular outer retainer 66 is fixedly joined to the second rabbet 50 to  
4 axially trap the liner aft flange 56 around the second rabbet. The outer retainer 66 may be a  
5 full ring with a single split, or may be a ring segmented in multiple sections from three to  
6 about eight. The individual retainer segments may be suitably tack welded to the second  
7 rabbet 50 on the aft side of the liner aft flange 56 opposite to the forward radial shoulder of  
8 the second rabbet. Similarly, the inner retainer 64 is preferably a full ring disposed on the aft  
9 side of the shell aft flange 44 opposite to the radial shoulder of the first rabbet 40 on the  
10 forward side of the shell aft flange.

11 **[0029]** In this way, the inner liner 54 illustrated in Figure 1 is concentrically mounted  
12 around its supporting shell 42 which in turn is concentrically mounted around its supporting  
13 casing 32 which in turn is suspended by the outer casing 30. The inner liner 54 and its  
14 supporting inner shell 42 are both mounted at their aft ends to the casing aft flange 34 for  
15 permitting differential thermal expansion and contraction relative thereto during operation.

16 **[0030]** In operation, combustion gases 22 are generated in the combustion chamber 60 and  
17 effect a decreasing temperature gradient from the liners to their supporting shells and in turn  
18 to the supporting inner casing 32. These components are annular or conical elements subject  
19 to both radial expansion and contraction as well as axial expansion and contraction. The  
20 inner liner 54 and the inner shell 42 are free to expand and contract relative to their  
21 supported aft ends and thereby experience relatively low thermal stress due to differential  
22 thermal movement therebetween. And, the aft mounting of the inner liner and its supporting  
23 shell ensures concentricity thereof relative to the engine centerline axis 12, and with the HP  
24 nozzle.

25 **[0031]** As illustrated in Figure 1, the inner retainer 64 forms a portion of the support for the  
26 turbine nozzle of the HPT 24. Accordingly, the inner combustion liner 54 and the turbine  
27 nozzle are commonly supported from the casing aft flange 34, and concentricity  
28 therebetween may be maintained for ensuring accurate radial alignment of the combustion  
29 gases 22 as they flow between the stator vanes of the turbine nozzle during operation.

1   **[0032]**     The various components of the combustor should be suitably mounted for  
2   maintaining the various alignments required therebetween for enhanced performance of the  
3   combustor during operation. The concentricity of both outer and inner combustion liners  
4   with the HP turbine nozzle is a significant design objective.

5   **[0033]**     Additional alignment is also required in the combustor. In particular, the casing  
6   header 38 includes a row of fuel injectors 68 suitably mounted through corresponding  
7   apertures 70 therein. Correspondingly, the dome 48 includes a row of air swirlers 72  
8   suitably mounted in corresponding apertures 74 in the dome.

9   **[0034]**     The fuel injectors and air swirlers may have any conventional configuration, with  
10   the fuel injectors being configured for injecting fuel through the center of the corresponding  
11   swirler, which typically includes two rows of counterrotating radial vanes which swirl the  
12   pressurized compressor air in two counterrotating streams around the injected fuel for  
13   atomization thereof for efficient combustion in the combustion chamber.

14   **[0035]**     Since the fuel injectors 70 are mounted in the casing header 38 and the air swirlers  
15   72 are mounted in the casing dome 48, suitable alignment therebetween is required for  
16   proper assembly and performance of the combustor.

17   **[0036]**     More specifically, a plurality of tabs or keys 76 as shown in Figures 2 and 3 are  
18   mounted in respective grooves or slots 78 between the shell aft flange 44 and the first rabbet  
19   40 for maintaining circumferential alignment between the apertures 70,74 in the header 38  
20   and dome 48 for corresponding alignment of the fuel injectors in their respective air swirlers.

21   **[0037]**     In a preferred embodiment, the keys 76 are fixedly mounted, by brazing for  
22   example, in the corresponding mounting grooves formed in the radially inner surface of the  
23   shell aft flange 44. And, the complementary alignment slots 78 are disposed in the first  
24   rabbet 40 and face radially outwardly in radial alignment with the corresponding keys 76.  
25   Although the keys 76 could be integrally formed with the shell aft flange 44, it is more  
26   practical and economical to separately manufacture the keys and fixedly mount them in the  
27   flange.

28   **[0038]**     Three keys 76 are used in the preferred embodiment and have an unequal  
29   circumferential spacing varying slightly from 120 degrees apart to ensure that the inner shell

1 42 may be assembled on the inner casing 32 in a single orientation, which in turn ensures  
2 proper alignment of the fuel injectors and air swirlers in their corresponding apertures. The  
3 three keys extend radially outwardly from the engine centerline axis and permit unrestrained  
4 differential thermal expansion and contraction in the radial direction.

5 **[0039]** The keys may be suitably small for preventing relative rotation between the inner  
6 shell and its supporting inner casing, yet may be sized sufficiently large for accommodating  
7 external loads expected in the vehicle mounting of the gas turbine engine. A  
8 vehicle-mounted engine is subject to various shock loads as the vehicle travels over rough  
9 terrain, especially in a high speed military application. Accordingly, each key 76 is  
10 preferably designed for withstanding the maximum expected external loads due to vehicle  
11 movement without failing. The multiple keys therefore provide failsafe redundancy in load  
12 support, as well as suitably clocking or indexing the circumferential alignment between the  
13 inner shell 42 and the inner casing 32.

14 **[0040]** As shown in Figures 2 and 3, the combustor preferably also includes a plurality of  
15 axial pins 80 mounted in respective cylindrical sockets 82 between the liner aft flange 56 and  
16 the second rabbet 50 for maintaining circumferential alignment between conventional  
17 dilution holes 84 provided in the inner liner. Both outer and inner combustion liners include  
18 patterns of inclined film cooling holes for channeling a portion of the compressed air 16 for  
19 cooling thereof in a conventional manner. And, both liners also include relatively large  
20 dilution holes, such as the row of dilution holes 84 illustrated in the inner liner of Figures 1  
21 and 3.

22 **[0041]** The dilution holes are circumferentially aligned with the corresponding fuel  
23 injectors and swirlers for minimizing hot streaks from the combustion gases discharged  
24 therefrom during operation. Alignment of the dilution holes with the corresponding swirlers  
25 is therefore required for proper performance of the combustor, and such alignment is  
26 effected by the complementary mating pins 80 in their alignment sockets 82.

27 **[0042]** As shown in Figures 2 and 3, the pins 80 are preferably fixedly joined, by welding  
28 for example, to the inner shell 42 to extend radially outwardly over the second rabbet 50  
29 from the forward shoulder thereof. Correspondingly, the sockets 82 are cylindrical apertures

1 disposed axially through the liner aft flange 56 in axial alignment with the corresponding  
2 pins.

3 **[0043]** In the preferred embodiment, three pins are disposed with unequal circumferential  
4 spacing varying slightly from 120 degrees apart around the circumference of the forward  
5 shoulder of the second rabbet 50. In this way, the dilution holes 84 provided in the inner  
6 liner 54 may be maintained in circumferential alignment with the corresponding air swirlers.  
7 The unequally spaced pins 80 ensure one and only one proper assembly position of the inner  
8 liner on its supporting inner casing.

9 **[0044]** Since the expected loads between the inner liner and its supporting casing are  
10 relatively low, the simple pins 80 may be used instead of the stronger keys 76 at this  
11 location. Accordingly, the pins 80 may have any suitable configuration for their location at  
12 the second rabbet 50 and for the expected loads thereat. Similarly, the keys 76 may have any  
13 suitable configuration for the expected loads at the first rabbet 40.

14 **[0045]** As initially illustrated in Figure 1, the inner casing 32 is generally toroidal due to its  
15 C-shaped axial section. The header 38 portion of the inner casing is thusly disposed axially  
16 forward of both the first and second end flanges 34,36 thereof for receiving the inner shell 42  
17 forward of the casing aft flange 34. And, the inner shell 42 is spaced radially outwardly  
18 from the inner casing 32 to define an annulus 86 therebetween through which the pressurized  
19 air 16 is channeled for flow through the inner wall of the combustor.

20 **[0046]** As shown in Figures 2 and 3, the shell aft flange 44 preferably includes a row of  
21 axial bypass holes 88 disposed in flow communication with the casing annulus 86 for  
22 channeling a portion of the air 16 axially therethrough.

23 **[0047]** As indicated above, the inner retainer 64 is conveniently provided by a suitable  
24 portion of the annular support for the HP nozzle. The retainer includes a radially inner  
25 portion which is suitably fastened by bolts to the casing aft flange 34, and includes a radially  
26 outer portion in which the stator nozzle is mounted.

27 **[0048]** The inner retainer 64 as illustrated in Figure 2 also includes a row of generally  
28 axially disposed apertures 90 extending through the radially outer flange thereof, and  
29 circumferentially aligned with respective ones of the bypass holes 88. In this way, the

1 pressurized air 16 may be metered through the bypass holes 88 for providing pressurization  
2 in the annular cavity defined between the inner band of the HP nozzle and its inner support.  
3 As shown in Figure 2, the small radial flange of the inner retainer 64 through which the  
4 apertures 90 are provided is an otherwise conventional feature for supporting a leaf seal (not  
5 shown).

6 **[0049]** The dual rabbet mounting of the inner liner 54 and the inner shell 42 to the  
7 cooperating inner casing 32 enjoys simplicity of construction and the several benefits  
8 described above including concentricity of the combustion chamber with the HP nozzle  
9 while maintaining accurate circumferential alignment of the simply mounted inner liner and  
10 inner shell. As shown in Figure 2, the shell aft flange 44 is radially supported on the first  
11 rabbet 40 and axially trapped between the inner retainer 34 on one side and the shoulder of  
12 the first rabbet on the other side. The manufacturing tolerances and clearances between  
13 these components may be relatively small for the direct trapping of the shell aft flange in the  
14 first rabbet without the need or desire for additional sealing members thereat.

15 **[0050]** Similarly, the liner aft flange 56 is radially supported around the second rabbet 50  
16 and axially trapped between the outer retainer 66 on one side thereof and the shoulder of the  
17 second rabbet 50 on the opposite side thereof. Again, the manufacturing tolerances or  
18 clearances may be relatively small for directly trapping the liner aft flange 56 around the  
19 second rabbet without the need or desire for additional sealing members thereat.

20 **[0051]** This nested duplex rabbet mounting of the combustor inner wall to the inner casing  
21 is relatively simple in configuration and enjoys the additional benefit of simple assembly,  
22 and disassembly for maintenance and repair. More specifically, Figure 3 illustrates  
23 schematically the assembly and corresponding disassembly of the inner combustor wall.  
24 The inner liner 54 itself is initially axially mounted around the inner shell 42 to seat the liner  
25 aft flange 56 in the second rabbet 50, while circumferentially aligning the several pins 80  
26 and their mating sockets 82.

27 **[0052]** The outer retainer 66 may then be conveniently welded in position on the exposed  
28 ledge of the second rabbet 50 following seating of the liner aft flange 56 in axial abutment  
29 against the rabbet shoulder.

1   **[0053]**   The inner shell 42, with the inner liner premounted thereon, is then axially mounted  
2   around the inner casing 32 to seat the shell aft flange 44 in the first rabbet 40, while  
3   circumferentially aligning the mating keys 76 and slots 78. The inner retainer 64 may then  
4   be axially mounted on the exposed shelf of the first rabbet 40 to axially trap the shell aft  
5   flange 44 in the first rabbet.

6   **[0054]**   In order to repair the combustor, for example by replacing the inner liner 54  
7   thereof, the assembly process may be reversed. The inner retainer 64 is axially removed  
8   from the inner casing 32 after the fasteners are disassembled. The inner shell 42 and inner  
9   liner 54 supported thereon may then be axially removed from the inner casing 32. The outer  
10   retainer 66 may then be removed from the second rabbet 50, by grinding of the tack welds  
11   for example, to then release the inner liner 54 from the second rabbet.

12   **[0055]**   The inner liner may then be removed from the inner shell and replaced with a new  
13   inner liner, with the assembly process then being repeated to reassemble the combustor with  
14   a new outer retainer 66, and either the originally used or new inner retainer 64.

15   **[0056]**   The double rabbet aft mounting of the annular combustor illustrated in Figure 1  
16   therefore enjoys various advantages in simplicity, assembly, disassembly, and maintenance  
17   repair. Concentricity between the combustion chamber and the HP nozzle and alignment of  
18   the fuel injectors, air swirlers, and dilution holes are ensured. And, pressurization air may be  
19   conveniently channeled through the bypass holes for pressurizing the inner cavity below the  
20   turbine nozzle.

21   **[0057]**   While there have been described herein what are considered to be preferred and  
22   exemplary embodiments of the present invention, other modifications of the invention shall  
23   be apparent to those skilled in the art from the teachings herein, and it is, therefore, desired to  
24   be secured in the appended claims all such modifications as fall within the true spirit and  
25   scope of the invention.

26   **[0058]**   Accordingly, what is desired to be secured by Letters Patent of the United States is  
27   the invention as defined and differentiated in the following claims in which we claim:
